Effect of Super-EBA as a Root End Filling on Healing after Replantation

The effect of Super-EBA cement as a root-end filling placed in teeth before replantation was examined in eight molar roots in monkeys. After extraction, root ends were resected, the canals contaminated with oral bacteria, root-end cavities prepared, and fillings of Super-EBA placed before replantation. After 8 wk, the jaws were removed and prepared for histological examination.

The tissue response to Super-EBA was very mild, with only a few inflammatory cells being observed at the root end of 3 of the 8 roots filled. Previous work showed a similarly mild response to Intermediate Restorative Material and a very much more severe response to amalgam.

It is concluded that the tissue response to Super-EBA as a root-end filling is acceptable and considerably more favorable than that to amalgam.

Super-EBA cements were developed in the 1960's as less irritant substitutes for zinc phosphate cements in restorative dentistry (1). They differ from other zinc oxide-eugenol cements in that the liquid contains 62.5% o-ethoxy benzoic acid, as well as eugenol. The compressive strength and solubility have been reported to be similar to zinc phosphate cement (1). In 1970, Hendra (1) advocated Super-EBA cement for root-end filling. Eight years later, Oynick and Oynick (2) reported that it had been used as a root-end filling in over 200 teeth, although detailed follow-up was not available.

In 1990, Dorn and Gartner (3) published the results of a retrospective clinical study of 65 teeth filled with Super-EBA and achieved a 95% success rate, considerably better than amalgam. Histological investigations appear to be absent apart from that of a single tooth by Oynick and Oynick (2).

The aim of this study was to investigate the tissue response to root end fillings of Super-EBA in an experimental model reported previously (4).

MATERIALS AND METHODS

The method has been reported in detail previously (4), but is briefly summarized. Mandibular first molars, which have two roots, were used in monkeys. Under general anesthesia, four teeth were extracted using gentle luxation movements. The root apices were resected flat with a diamond wheel under a constant flow of saline, before a 2-mm-deep root end cavity was drilled with a round bur (diameter 0.8 mm); the cavity was then washed and dried. Infection was introduced into the root canal before the root end was filled with Super-EBA cement (Staident, Staines, UK) mixed according to the manufacturer's instructions.

After completion of the root end filling procedure, the molars were replanted and left unsplinted for 8 weeks. The monkeys were then killed, and the jaw section was removed. The tissue blocks were fixed in formalin before being demineralized in EDTA. After embedding, the tissue blocks were sectioned and stained.

Sections were assessed for inflammation at the root end adjacent to the filling material. The severity of the inflammation was recorded as: none = no inflammatory cells, few cells = few inflammatory cells, moderate = inflammatory cells did not obscure the normal tissues, and severe = inflammatory cells replaced normal tissues. The extent of inflammation was recorded as ≤0.1, ≤0.2, ≤0.5, or >0.5 mm. The presence or absence of root resorption exposing the root end filling material was noted, and where present the greatest extent toward the crown was recorded as part of the length of the filling (to the nearest 1/4). The presence or absence of ankylosis of the tooth in any part, noticeable dissolution of the root-end filling material, giant cells, a fibrous capsule, cementum deposition on the filling material, epithelium covering the filling material, and bacteria in any part of the root canal were noted.

RESULTS

The severity and extent of inflammation around the root ends are reported in Table 1. Data for amalgam and Intermediate Restorative Material (IRM) (Caulk, Dentsply, Milford, DE) have been reported previously (4). All the roots filled with Super-EBA cement had inflammation in the none/few inflammatory-cell categories, in contrast to the other materials. However, the differences between IRM and Super-EBA were small and not significant (p > 0.05, χ² test). Figure 1 shows a root end filled with Super-EBA, and a very small number of lymphocytes can be observed in fibrous tissue.

DISCUSSION

The findings of this investigation with Super-EBA cement are broadly similar to those with IRM reported previously (4).

In view of the small number of roots involved, it would be unwise to conclude that the tissue response to Super-EBA was better than that to IRM. The results contrast with the severe response to amalgam (4). There is also agreement with radiographic studies of superior healing compared with amalgam (3, 5).

In common with IRM, more severe inflammation was noted at the sides of the roots where dentin had been resorbed. The resorption was more severe with Super-EBA cement. Although the resorption was without a doubt initiated by the procedure of extraction and replantation, it would seem possible that some substance may have been leached out of the Super-EBA cement enhancing the resorption. However, where the material was exposed to the tissues at the root end, the tissue response was very good, implying that no further substances were being leached out.

Because the root canals of most of the teeth were shown to be still infected at 8 wk, Super-EBA cement seemed to provide...
significantly less severe, and less extensive than that to amalgam.

Do you ever get the feeling that nothing’s simple any more? You’re right. Take herpes simplex virus, for example. A few cold sores when tissue is injured or you’re under stress—but in time you’ll grow out of it, right? That’s why it’s simplex. It has now been shown that herpes simplex virus is the most frequently isolated pathogen in the lungs of patients with severe respiratory disease (Scand J Infect Dis 24:283). Furthermore, HSV antibody-positive patients who are heart-lung transplant recipients are at considerable risk of pneumonia or other complications (Transplantation 49:735).

Even simplex isn’t simple any more.
